

Business Requirements Document (BRD)

Digital Banking Application

Version	1.1
Author	Britney Senaratne
Role	Business Process Associate
Date	May 09, 2026

1. Executive Summary

This document outlines the corrected functional requirements for the Digital Banking Application. The goal is to provide a secure and efficient platform for users to manage accounts and perform transactions while ensuring absolute data consistency with the Bank Core System.

2. Business Scenario

The application acts as the digital interface for the bank's core services. It must handle secure authentication and provide real time updates. A key operational constraint is the mandatory validation of funds before any debit transaction to prevent financial discrepancies.

3. Functional Requirements

ID	Requirement Description	Priority
FR-01	User Authentication: The system must verify user passwords through the Bank Core System. Display a descriptive error message upon incorrect credentials.	Critical
FR-02	Balance Inquiry: The system shall retrieve and display real-time account balances directly from the bank's central server.	High
FR-03	Fund Validation: The system MUST verify sufficient available funds before initiating any	Critical

	transfer or bill payment transaction.	
FR-04	Payment Source Selection: Users must be able to toggle between valid Checking and Savings accounts when performing bill payments.	Medium
FR-05	User Onboarding & Help: New users shall be presented with privacy policies and an option to access the profile help assistance module.	Medium
FR-06	Profile Management: Users shall have the ability to set up and manage their personal profiles, including privacy settings.	High

4. Stakeholder Roles (Actors)

- **Customer:** The primary end-user who interacts with the portal to manage finances.
- **Banking System:** The backend authority that validates credentials, confirms fund availability, and records transactions.

5. Operational Logic

The system follows a synchronous validation flow. Every transaction request triggers a "Sufficient Funds Check" against the Bank Core System. If the backend returns a failure, the transaction is immediately halted, and the user is notified, ensuring zero overdraft risk.
